

KAKUCS–BALLA-DOMB

A CASE STUDY IN THE ABSOLUTE AND RELATIVE CHRONOLOGY OF THE VATYA CULTURE

Abstract: The present study hopes to contribute to Middle Bronze Age studies in two specific areas: first, by publishing a new series of radiocarbon dates for a period from which there are few absolute dates, and second, by describing a less known area in the Vatya culture distribution based on the investigations at Kakucs.

The Kakucs area was increasingly intensively settled during the course of the Bronze Age. In this context, the area along the left Danube bank down to the Kakucs area, lying in close proximity to the eponymous site at Újhartyán–Vatya, is very instructive. Following a scanty occupation marked by a few smaller sites at the onset of the Early Bronze Age, the number of sites and associated cemeteries grew dynamically from the late Nagyrév/early Vatya period onward. Despite the uncertainties in the relative chronology of the known Middle Bronze Age sites, the increase in the number of sites is in itself a reflection of a population growth and an increasing landscape exploitation. The left bank of the Danube became one of the period's most intensively settled regions during the Middle Bronze Age 1–3.

Keywords: Middle Bronze Age, tell settlements, Vatya ceramic style, Kakucs–Balla-domb, ¹⁴C chronology, absolute dating

INTRODUCTION

The settlements and the cemeteries in the central region of Hungary lying along the north to south Danube section are characterised by pottery made in the Vatya style during the Middle Bronze Age. This period corresponds to the RB A1/A2–RB B in the chronological scheme introduced by Paul Reinecke. In terms of absolute chronology, the Vatya sequence spans some 400 to 500 years between 2000/1900 and 1500/1450 BC.¹ Regarding ceramic styles and typology, this period starts with the Nagyrév/Vatya transition, continues with Vatya I–III and ends with the Koszider period according to the conventional scheme used in Hungarian Bronze Age studies.² Many settlements and cemeteries of the Vatya culture dating from these roughly five hundred years are known from the fundamentally differing environments characterising Northeastern and Eastern Transdanubia, the Danube region and the Danube–Tisza interfluvium. Several studies have been devoted to the culture's cemeteries,³ as well as to the multi-tiered Vatya

settlement network made up of fortified hillforts, stratified tell settlements (*Fig. 1*) and open settlements.⁴ The period's perhaps best-investigated region is the Százhalombatta area⁵ and the Benta Valley⁶ west of the Danube. The number of known sites has increased manifold as result of continuous field surveys and excavations. The publication of the already investigated sites will no doubt contribute to drawing together the evidence on Vatya settlements and to adding finer details to the broad picture of how Vatya settlements evolved, as well as to the dynamics of their growth and the diachronic changes in settlement patterns.

The present study hopes to contribute to Middle Bronze Age studies in two specific areas: first, by publishing a new series of radiocarbon dates for a period from which there are few absolute dates, and second, by describing a less known area in the Vatya distribution based on the investigations at Kakucs. The environment of the region south of Budapest and east of the Danube was largely determined by the channels of the palaeo-Danube during the successive archaeological and historical periods.⁷ The bluffs overlooking the rivers and the larger islets were dotted with Middle Bronze Age settlements and cemeteries, among them the stratified tell settlements of Balla-domb and Szélmalom-domb on the outskirts of Kakucs, which were probably one of the centres in the settlement network of this region during the earlier 2nd millennium BC.

THE BRONZE AGE LANDSCAPE IN THE KAKUCS AREA

The study area extends to Dömsöd along the Danube section south of Budapest and is bounded by the Soroksár–Gyál–Kakucs line in the east (*Fig. 2*). Administratively, the area is part of the southern district of County Pest and it incorporates sections of various micro-regions, among them the southerly alluvial fan of the Pest Plain, the eastern half of the Csepel Plain and, moving further to the east, the Pilis–Alpár sand dunes and the Kiskunság sand dunes of the Danube–Tisza interfluvium.⁸ Towards the east, the Csepel Plain gradually rises from the floodplain of the Danube Valley towards the higher-lying terraces (95–168 m a.s.l.), whose eastern margins are covered with alkaline grassland (Apaj) and wind-blown sand (Sári [Dabas], Kunpeszér). Lying farther to the east is the Pest alluvial fan on the northern fringes of the Danube–Tisza interfluvium. The area is wedged in-between the Gödöllő Hills and the Csepel Plain (98–251 m a.s.l.). The mosaic of the terraces rising toward the east is criss-crossed by the Danube's left bank tributaries. The areas lying to the south and south-west are characterised by lower-lying terraces covered with wind-blown sand (Kiskunság and Pilis–Alpár sand dunes). The area lies at the interface of the continental, the sub-Mediterranean and the Atlantic climate zones. In terms of vegetation, it can be assigned to the Pannonian forested steppe region.⁹

Dissected by the Danube, the palaeohydrography of the alluvial fan of the Pest Plain differed substantially from the modern one. The river's alluvial fan in the Pest area suggests that the Danube's course gradually changed during the Pleistocene and the Early Holocene, and that it attained its current channel with a 90° westward rotation. Concurrently with the gradual shift in the river's course and the accumulation of the river terraces, the area was criss-crossed by countless spill streams and side-branches. Dividing into several branches, the river moulded the environment unhindered until the large-scale regulations. The river frequently shifted its course before the 19th–20th century regulation: meander loops appeared and disappeared, bars were formed and eroded, and the side-branches too changed their course, with new ones evolving and earlier ones partially infilling. Palaeoenvironmental and ecological studies on the Bronze Age landscape are only partially available.¹⁰

The remnants of an ancestral Danube channel between Ócsa and Inárcs to the south of Budapest appears as *Sárvíz* [Sár/Mud waters] or *nagy Sár folyó* [Great Sár/Mud River] in 13th century charters.¹¹ Antal Balla's hydrological map from 1793 shows the river with a wide floodplain coursing through a waterlogged area between Budapest–Soroksár and Kalocsa.¹² The branches of the extensive marshland preserved their freshwater nature for a long time. Fishing and milling places can be identified from the medieval and post-medieval records, and water mills were still active in the region a few generations before the river regulations in the 1920s.¹³ The 18th century maps depicted a world of lakes and marshes on the western outskirts of Ócsa, Inárcs, Kakucs and Dabas, between Bugyi, Sári, Gyón, Kunszentmiklós and Dömsöd. Various islets rose above the river at Bugyi–Ürbő for example,¹⁴ and one could still travel from Ürbő to Kalocsa by boat in the late 19th century.¹⁵ No more than a handful of sand islands were suitable for settlement in a region which could only be approached by boat for the greater part of the year. Medieval documents recount the continuous efforts to create protection against floods and backwater. The problem of drainage was eventually resolved by a network of artificial channels from the 1910s–1920s. The 150 km long Danube Valley Main Channel was also created at this time.

A waterlogged area dotted with bogs extends along the boundary of the Danubian plainland and the sand dunes of the Danube–Tisza interfluve. The Ócsa peat-bog is the northernmost bog in this bog sequence. The bogs changed dynamically through the ages: at times, they were deep lakes with crystal clear waters, at times they became infilled and their surface was covered with aquatic plants. The palaeoenvironmental investigation of the Ócsa peat bog at *Selyemréti* indicated a gradual decrease in the surrounding woodland between the Late Neolithic and the Early Bronze Age accompanied by soil erosion, as a result of which the inflow of humus into the Ócsa sediment catchment intensified and eventually led to its infilling.¹⁶

THE MIDDLE BRONZE AGE SETTLEMENT NETWORK ON THE LEFT DANUBE BANK: THE KAKUCS AREA

It is clear from the above broad geographic description that there was another channel that gradually succumbed to eutrophication some 50–60 km from the Csepel Island–Ráckeve/Soroksár Danube main channel which undoubtedly determined the area's environmental potentials. Although the area has not been systematically surveyed, the currently available information seems sufficient for a broad reconstruction of the one-time landscape exploitation.

The area was increasingly intensively settled during the course of the Bronze Age.¹⁷ In this context, the area along the left Danube bank down to the Kakucs area, lying in close proximity to the eponymous site at Újhartyán–Vatya, is very instructive. Following a scanty occupation marked by a few smaller sites at the onset of the Early Bronze Age, the number of sites and associated cemeteries grew dynamically from the late Nagyrév/early Vatya period onward.¹⁸ Despite the uncertainties in the relative chronology of the known Middle Bronze Age sites (mostly due to the lack of excavation on these sites), the increase in the number of sites is in itself a reflection of a population growth and increasing landscape exploitation. The left bank of the Danube became one of the period's most intensively settled regions during the Middle Bronze Age 1–3.

For a very long time, mostly cemeteries were known from the geographic centre of the Vatya heartland, i.e. the region extending south of Budapest along the Danube. The culture's eponymous site at Újhartyán–Vatya-puszta¹⁹ lies in this area. There has been a welcome increase in the number of Middle Bronze Age sites because several new settlements and burial grounds were discovered during the past decades.²⁰ The central hillforts fortified by enclosures, such as the ones at Soroksár–Várhely²¹ and Dömsöd–Leányvár,²² and the associated open settlements formed the backbone of the Vatya settlement network which, on the testimony of the field survey data, also com-

prised smaller villages and farmsteads such as the one recorded at Gyál²³ (*Fig. 2*). In addition to the settlements, a series of larger and smaller cemeteries are also known.²⁴

The Kakucs area is one of the more intensely investigated micro-regions. Although the area has not been systematically surveyed, Bronze Age finds have been continuously found and reported from this area since the 1900s. The currently known two largest, most extensive sites in the area are Kakucs–Balla domb and Kakucs–Szélmalom domb. Several smaller settlements, such as the one at Újhartyán–Földék, have been identified along the one-time river channel within a 0.1–1 km radius of the central settlement extending over two (or perhaps even three) elevations. Larger settlements, similarly protected by enclosures, are known within a 10 km radius of the Kakucs–Balla domb site: the settlement at Kakucs–Turján mögötti-dűlő/Dunavölgyi főcsatorna dél lies some 3 km to the west,²⁵ Dabas–Dabasi Szőlők 6 km to the south,²⁶ and the cemetery and settlement of the eponymous site at Újhartyán–Vatya-puszta can be found to the east.²⁷ A chain of settlements and burial grounds can be found towards the north-east, marked by the sites at Inárcs, Ócsa, Dabas–Belső Mántelek, Dabas–Sári, Bugyi and Alsónémedi (*Fig. 2*).²⁸

KAKUCS–BALLA–DOMB: THE BRONZE AGE SETTLEMENT

The remains of an extensive settlement extend across two large hills rising above the former Tó-környék marshland on the south-western outskirts of Kakucs. The two hills are located on the left side of the Danube Valley Main Channel draining the area. The smaller hill is known as Balla-domb, the larger one to its south-west is called Szélmalom-domb (*Fig. 3*). The Szélmalom-domb is marked on the maps of the First and the Second Ordnance Survey conducted in 1780–1784 and 1829–1867, respectively (*Fig. 3.1*).

We collected various finds indicating occupation during the Bronze Age on the Szélmalom-domb, currently under cultivation, during the field survey conducted in 1991. The same year, we were informed by L. Czagányi that various prehistoric artefacts had regularly come to light during construction and gardening work on the steep hillside between Fő út and Malomkert út.²⁹ In 1992–93, we therefore conducted a rescue excavation in an area known as the Balla plot that would soon be built up, but was still undisturbed at the time. The site was named Balla-domb after Ferenc Balla (†), the former director of the elementary school, who owned the plot on the hilltop. Rising some 5–6 m above the surrounding area, the built-in, roughly oval hill has a diameter of *ca.* 125 m. Adjoining it from the south-west is the Szélmalom-domb, a larger hill measuring 250 m by 250 m that gradually spreads out towards the south-west and grades into the lower-lying plain once covered with water. The two hills were probably once part of the same settlement. Judging from the surface finds, a third hill, the so-called Liebner-domb on the other side of Fő út, was probably also part of the same settlement centre. Traces of other settlements were identified on the opposite side of the Danube Valley Main Channel, on the outskirts of Újhartyán in an area known as Külső földek during the field survey conducted in 2010.³⁰

All traces of an earthen rampart and ditch around and between the Szélmalom-domb and the Balla-domb have disappeared. However, it must be noted that two modern streets (Fő út and Malomkert út) run in a depression between and around the two hills. These may have been natural depressions, but they may equally indicate the location of the one-time enclosures protecting the settlement.

The settlement features and their chronology

In 1992–93, we opened two trenches in the relatively undisturbed and unbuilt areas: one in the hill's central, highest area (Trench A, 10 m by 10 m) and another one on the north-eastern slope (Trench B, 4 m by 5 m) (*Fig.*

3.3–4).³¹ In 2010, we had the opportunity to submit ten samples for radiocarbon measurements (*Table 1*).³² We selected animal and human bone samples recovered from Trench A and thus the dates obtained from the measurements will be included in the description of the excavated settlement section. We strove to select samples from well-definable features, such as burials, animal bones embedded in wall remains and securely identifiable pits. Even so, knowing the nature of stratified tell settlements, there was a fair risk of mixing between the finds, as will be shown below.

We distinguished four occupation levels characterised by house plans with a plastered floor in the 1.5 m thick layer sequence between the earliest pits dug into the prehistoric humus level and the sub-humus/uppermost mixed deposit overlying the settlement (Fig. 4). The settlement was occupied from the late Nagyrév/early Vatya to the Vatya III/Vatya–Koszider period. Most Vatya settlements are characterised by an abundance of pits, perhaps indicating the shift of various activity areas within the settlement.³³ The presence of so many pits usually makes the exact separation of occupation levels somewhat difficult, and the Kakucs site was no exception. We divided Trench A into 2 m by 2 m squares and then proceeded to excavate and record the various features according to the one-time occupation levels.

The 40–50 cm thick strongly disturbed topsoil mixed with modern debris was removed mechanically. The loose earth of the underlying 30–35 cm thick sub-humus layer was mixed with the debris of the uppermost deposit of the Bronze Age settlement, and contained a rich assortment of Bronze Age, medieval and modern artefacts. This was

³¹ The preliminary assessment of the finds was part of an MA thesis, KULCSÁR 1995b.

³² Samples for radiocarbon measurements were collected as part of M. Jaeger's PhD thesis. The samples were submitted to the Radiocarbon Laboratory in Poznań, through a grant from Poland.

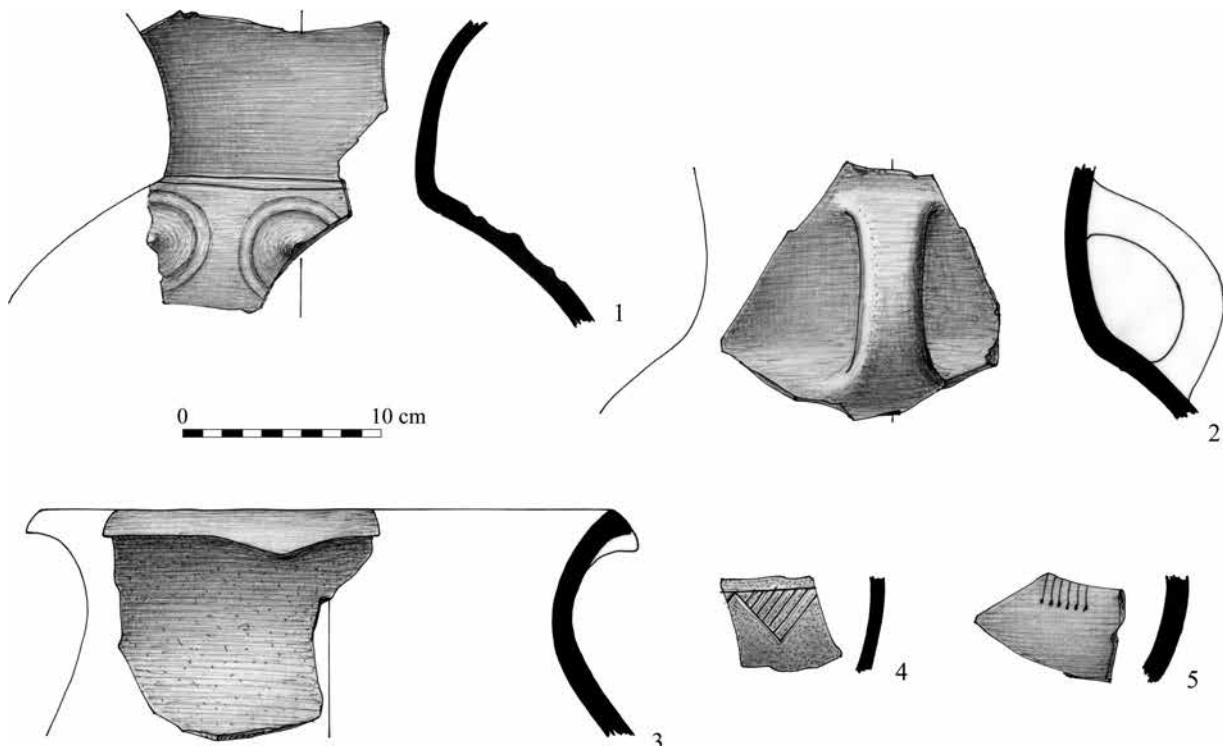

Fig. 7. Kakucs–Balla-domb. 1–5: Selection of finds from Unit A/3/2 of Level 1

followed by the settlement's uppermost deposit, which covered Level 1 of the settlement. The soil marks of several pits indicating the end of the Bronze Age occupation could be noted in this deposit. It was often difficult to precisely observe the outlines of these pits in the greyish, mixed surface of the uppermost deposit. We attempted to distinguish individual pits by carefully proceeding downward. The exact outline of the pits could be recorded in Level 1, where the pits intruded into the plastered floor of the one-time buildings. However, owing to the pits, we were unable to distinguish individual house plans and could only document the fragments of the plastered floors and a few surviving *terre pisé* walls (Fig. 5). On the testimony of the finds, the uppermost deposit and Level 1 could be assigned to the Vatya III and the Vatya III–Koszider period (Figs 6–8). Samples for radiocarbon dating were submitted from a crouched inhumation burial found in Pit "a", one of the largest pits uncovered in the trench (Feature A/3; Poz-36175; Fig. 5.1–2; Fig. 6, Table I).³⁴ The left-side crouched burial of an 18–20 years old juvenile male was SE–NW oriented and lacked grave goods.³⁵ The grave pit was clearly dug into the occupation level and was backfilled with earth mixed with settlement debris. The sample gave a date of 1526–1449 (68.2%) cal BC (Table 1). Level 1 can be dated to 1627–1532 (68.2%) cal BC on the testimony of a sample taken from one of the floors (Level 1, Section A/3/2; Poz-36177; Table 1, Fig. 7). Another sample from the same level gave a much earlier date: the sample from the 1–1.5 m long surviving section of a red burnt wall remain yielded a date of 1889–1772 (68.2%) cal BC (Level 1, Section A/Wall 1–2; Poz-36176; Table 1, Fig. 8).

Moving downward the traces of pits intruding from the overlying level could still be observed in Level 2. Level 2 was closely associated with Level 3 (Fig. 4; Fig. 9). The two buildings with a plastered clay floor uncovered in the two levels were erected in the same spot in both levels, the floor of the buildings was renewed in the same area and the refuse pits too lay in roughly the same area. The ceramic wares from Levels 2–3 can be predominantly assigned to the Vatya II (–III) period (Figs 11–12). The close association of the two levels is confirmed by the samples from the area of the successively rebuilt houses, which gave dates of 2010–1896 (68.2%) cal BC (Level 2,

³⁴ Pit "a" extended down to the lowermost level and cut into the prehistoric humus. We are able to distinguish different phases in its fill.

³⁵ We wish to thank Éva Susa for the anthropological evaluation.

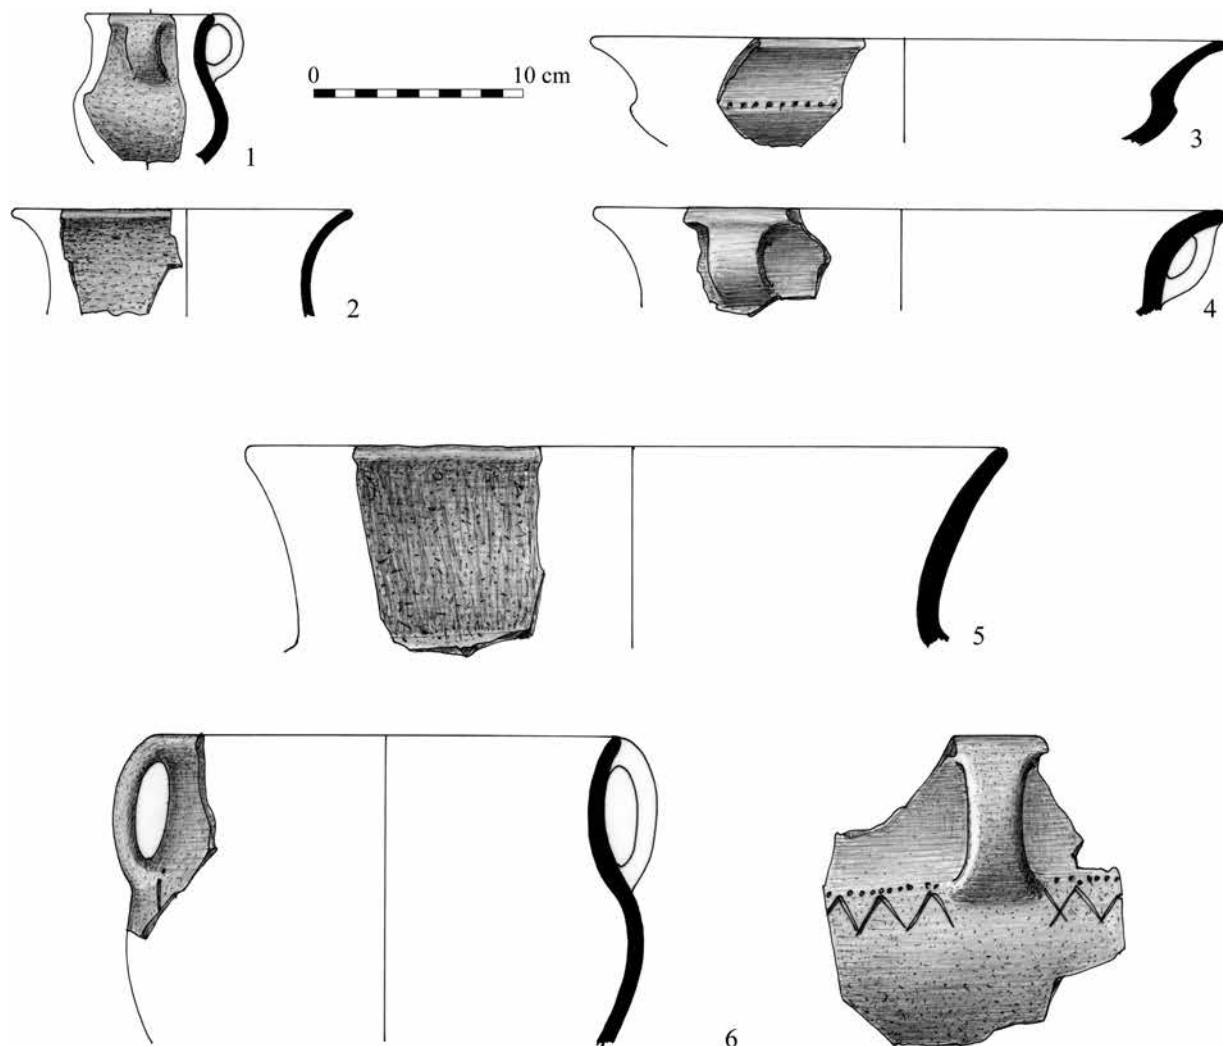

Fig. 8. Kakucs–Balla-domb. 1–6: Selection of finds from Unit A/3–5/1 of Level 1

Section A/3–5/1–3; Poz-36202; *Fig. 10*) and 2022–1919 (68.2%) cal BC (Level 3, Section A/3–5/1–3; Poz-36203; *Fig. 11*) (*Table 1*). The date of 1947–1782 (68.2%) cal BC (Level 2, Section A/5/3–4; Poz-36178; *Fig. 12*) for another contemporaneous house area in Level 2 fits into this sequence (*Table 1*). Feature 4–5, a pit, could be associated with this level (*Fig. 9.3–4*). The pit contained a halved, headless cattle body with the limbs placed on top of each other, as well as typical Vatya cups and other pottery sherds (*Fig. 13*). Samples from the cattle bones yielded a date of 1918–1777 (68.2%) cal BC (Feature A/4–5; Poz-36207) (*Table 1*). Pit 9, a beehive shaped pit which reached to the prehistoric humus level (*Fig. 16.1*), can be linked to the early phase of Level 3, as shown by the presence of both early Vatya and Vatya II/III pottery among its finds (*Figs 14–15*). The date for this pit, 2022–1919 (68.2%) cal BC (Pit A/9; Poz-36204), represents an earlier occupation phase (*Table 1*).

Level 4 was characterised by houses with a plastered clay floor erected directly on the prehistoric humus level (*Fig. 4*; *Fig. 16.2*). We found the remnants of clay floors separated by gaps which, however, were not pits, but a “street” littered with debris and refuse. The floors were renewed once or twice with fresh plastering. It is difficult to reconstruct the rhythm of the rebuilding activity after the occupation phase represented by Level 4 because in some areas, the surface was levelled and covered with a 25–30 or even 40 cm thick mixed, brownish-grey layer, while in others, the use of earlier buildings continued. The dynamic shift in activity areas could be noted in all phases of the settlement’s occupation. Pit 15 can be associated with the late phase of Level 4. The rather late date

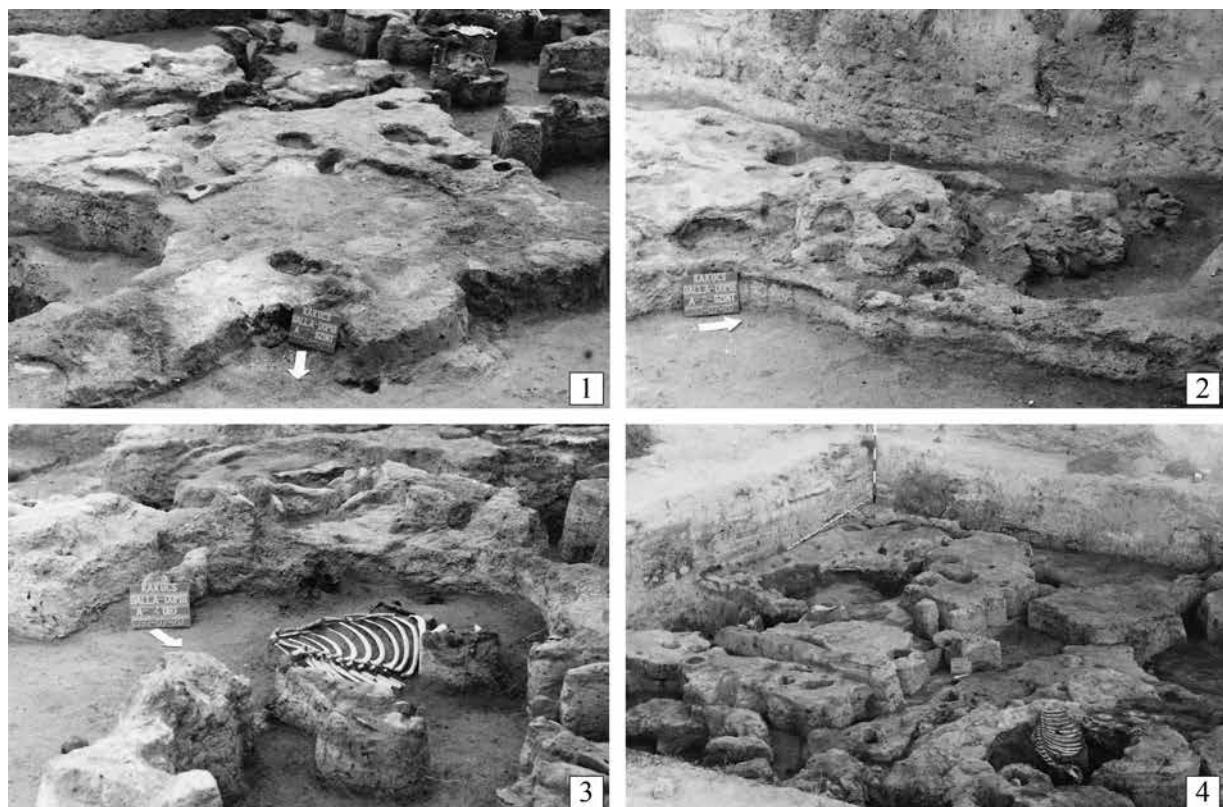

Fig. 9. Kakucs–Balla-domb. 1–2: Level 2; 3: Feature A/4–5; 4: Level 3 with Features A/4–5

obtained for this feature, 1877–1744 (68.2%) cal BC (Pit A/15; Poz-36206; *Table 1, Fig. 17*) perhaps indicates that finds from a later period had intruded into Pit 15 from later pits (see Feature A/4–5) either during the excavation or during the settlement's occupation.

The earliest phase of the Kakucs–Balla-domb settlement is indicated by the pits dug into the dark brown prehistoric humus level, which was reached at a depth of 230–240 cm from the 0 point (*Fig. 4; Fig. 16.3*). This 70–100 cm thick prehistoric humus level overlies the hill's geological bedrock. Seventeen pits and several post-holes could be identified in the prehistoric humus level. Seven pits represented the settlement's earliest occupation, while the other pits were dug into the humus from a later, higher-lying level. The finds indicate that the artefactual material from the earliest pits and from Level 4 cannot be sharply distinguished because both contain late Nagyrév/early Vatya and Vatya I ceramics. We decided to date a sample from Pit 14 because it contained very typical early Vatya material (*Fig. 4; Fig. 18*). Surprisingly enough, the date of 1956–1881 (68.2%) cal BC (Pit A/14; Poz-36205) was closer to the dates from Levels 2–3 (*Table 1*).

In sum, the typochronological and stratigraphic evidence shows that the settlement was occupied continuously from the late Nagyrév/early Vatya transition to the Vatya III and Vatya–Koszider period, spanning the period between the turn of the Hungarian Early Bronze Age 3/Middle Bronze Age 1 and the close of the Middle Bronze Age 3 in the relative chronological framework. This corresponds to the RB A1/A2–RB B period. The currently available absolute dates for the Kakucs settlement indicate that the site was occupied between 2022–1919 and 1627–1532 (68.2%) cal BC, although the date of the burial, 1526–1449 (68.2%) cal BC, must also be considered (*Table 1, Fig. 19*). The detailed assessment of the finds and of the settlement layout will no doubt contribute to a finer periodization of the Vatya ceramic style. One point that emerges clearly is that problems caused by the mixing of the finds on a tell settlement can only be prevented by very precise sampling. An explicit correlation between ceramic styles and absolute chronological dates is not possible, in part owing to the continuous changes in the settlement's layout and the lack of burnt destruction levels, and in part to the margin of error of the radiocarbon dates.

NOTES ON THE ABSOLUTE CHRONOLOGY OF THE FORTIFIED SETTLEMENTS OF THE VATYA CULTURE

The wide-ranging issue of the Bronze Age chronology of the Carpathian Basin is a problem that would deserve a separate study. The most important studies seeking to reconcile the chronological schemes constructed before World War 2 and during the later 20th century have been described in detail by W. David.³⁶ These schemes were based solely on stratigraphic observations made on settlement and cemetery sites, and on the typology of pottery and metal artefacts, the latter including hoards.³⁷ The main reason for this situation is the low number of radiocarbon dates.³⁸

Our main concern here is the chronology of the fortified settlements of the Vatya culture and of the Koszider horizon, traditionally regarded as marking the end of the so-called tell cultures (amongst them, the Vatya culture). In the conventional Hungarian chronological framework, the so-called Koszider period (RB B, ca. 1600–1500/1450 BC) corresponds to the last phase of the Middle Bronze Age and, at the same time, it also represents the transition to the Late Bronze Age. The interpretation of this period is hotly debated among archaeologists working in Hungary and in the westerly regions of Central Europe. The deposition of the so-called Koszider hoards was traditionally linked to the attacks of the mobile pastoralist warriors of the “Tumulus culture” arriving from Southern Germany, whose arrival brought an end to the flourishing “tell cultures” along the Danube and the Tisza.³⁹ In this interpretation, the Koszider period was regarded as brief interlude of turbulence and war, which was followed by the classical Tumulus period (RB C, ca. 1500/1450–1300 BC). More recently, however, the period is not seen as a

³⁶ DAVID 2002, 3–46. It is symptomatic that the author did not use any of the chronological systems he referred to, and instead employed the classical terminology of the scheme proposed by P. Reinecke.

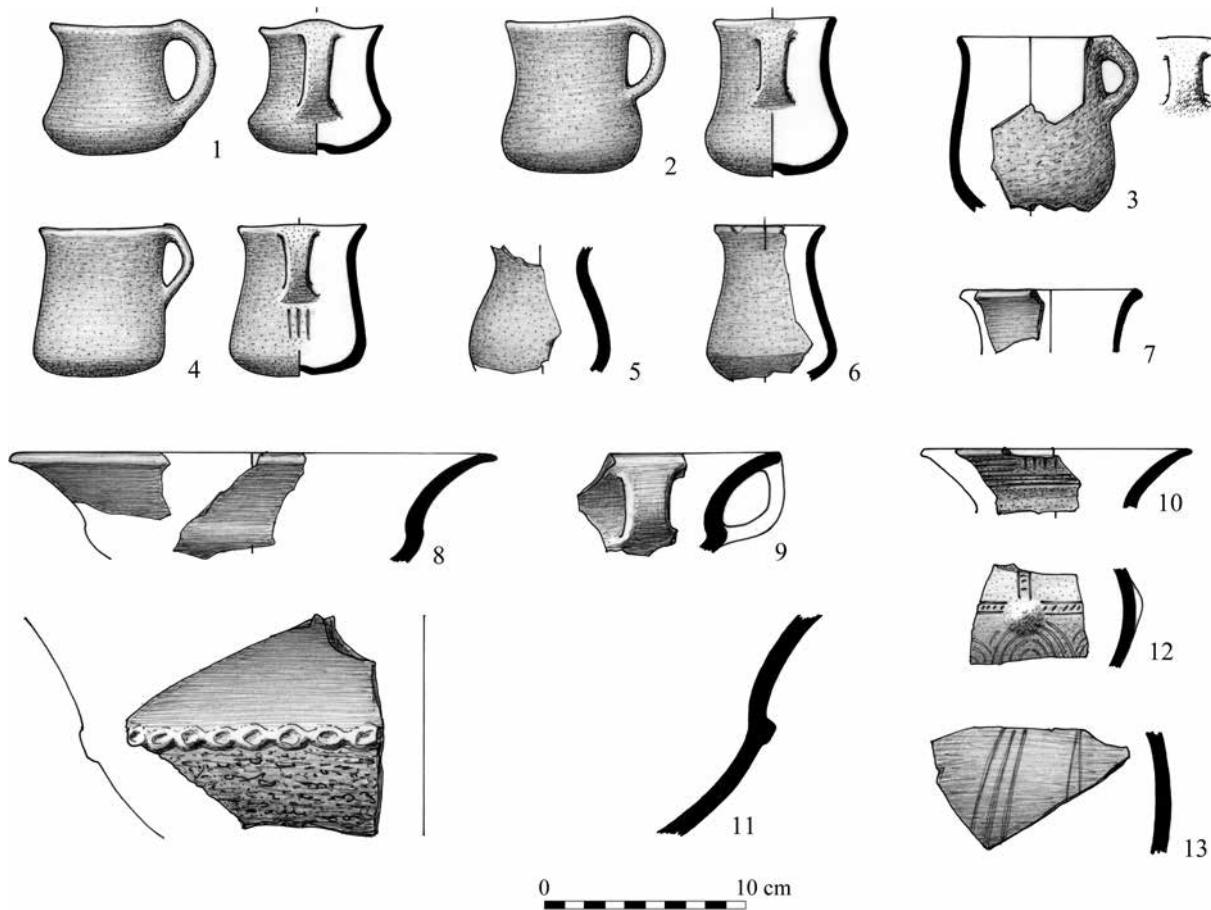

Fig. 14. Kakucs–Balla-domb. 1–13: Selection of finds from Pit A/9

“horizon” linked to a specific set of events, but rather as a longer period representing a cultural peak in the Bronze Age of the Carpathian Basin, whose end was marked by profound transformations.⁴⁰

The classical periodization of the Vatya culture into three phases, Vatya I (sub-phases a and b), Vatya II and Vatya III, was proposed by I. Bóna.⁴¹ He correlated the three sub-periods with the main divisions of the Middle Bronze Age he had distinguished.⁴² The Vatya sequence ends with the Koszider period.⁴³ Although I. Bóna had originally assigned this period to the Late Bronze Age, it is now generally associated with the Middle Bronze Age.⁴⁴

According to the generally accepted Hungarian chronological framework, as elaborated by T. Kemenczei, T. Kovács and N. Kalicz, the emergence of the Vatya culture (Vatya I) is linked to the onset of the MBA 1, Vatya II roughly corresponds to the MBA 2, while MBA 3 can be equated with the culture’s late variants (Vatya–Koszider, Alpár, Rákospalota).⁴⁵

⁴¹ BÓNA 1975, 25, 73; cp. KREITER 2007, 33.

⁴² Cp. KOVÁCS 1984, 223.

⁴³ The controversies concerning the Koszider horizon are reflected in the labels attached to this period. It is variously referred to as Vatya–Koszider horizon, period, phase or even culture (MOZSOLICS 1988, 42; BÓNA 1992b, 58–64, with additional literature) and the label is then used to describe discrete phenomena such as the deposition of hoards and settlement development. This picture is fur-

ther complicated by the ever-growing number of cultural groups, which are then used as synonyms for the Koszider horizon: e.g., Streda nad Bodrogom/Bodrogszerdahely phase (Otoman–Füzesabony culture), Alpár phase, Rákospalota phase (Vatya culture) (cp. BÓNA 1992a, 17).

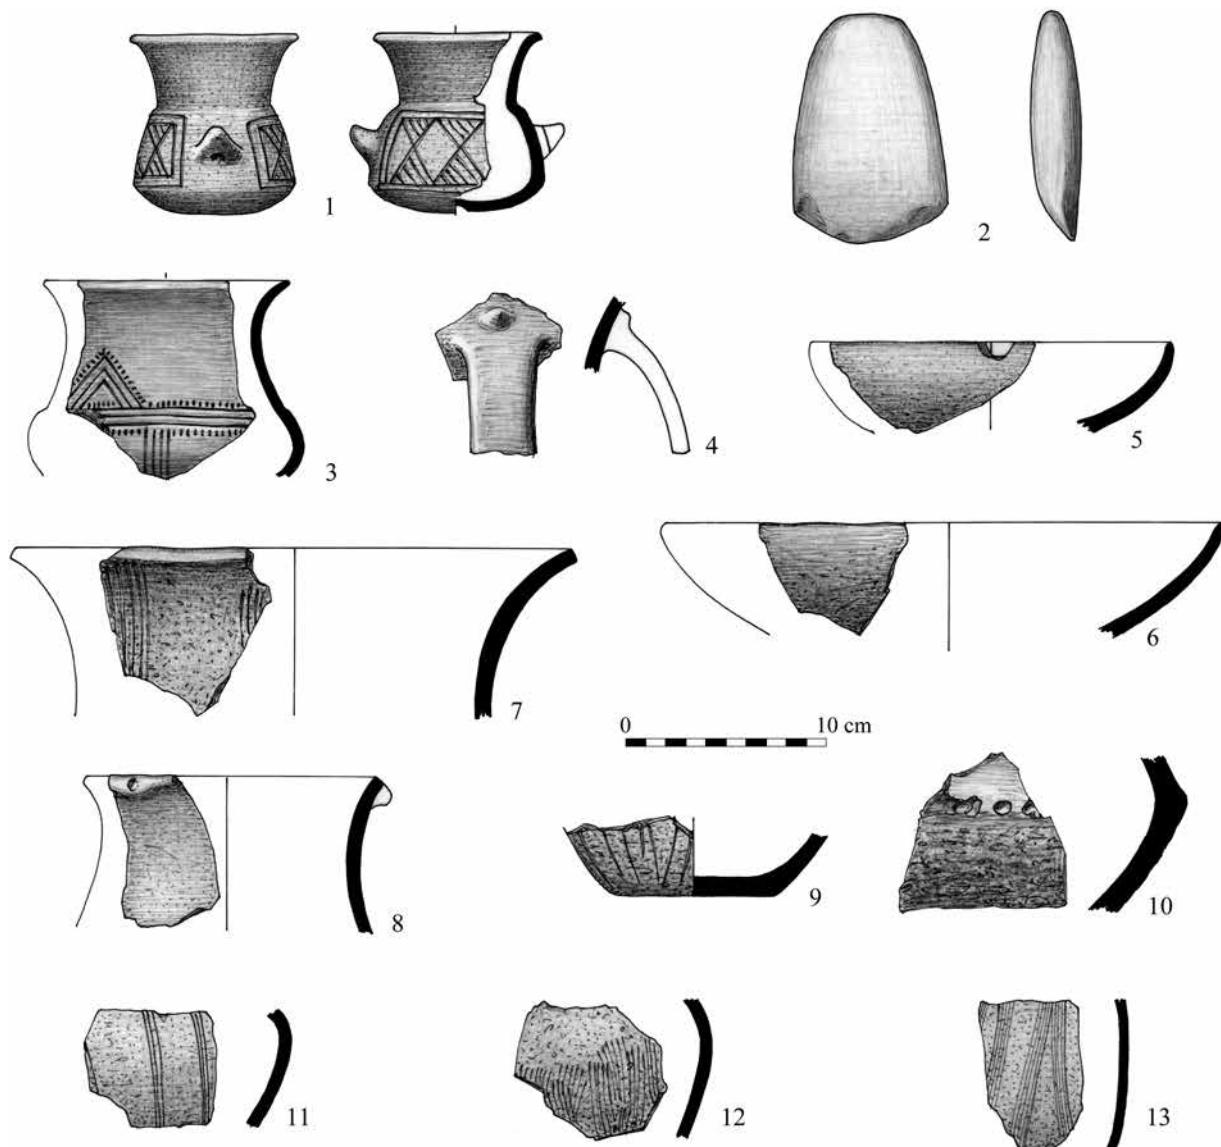

Fig. 18. Kakucs–Balla-domb. 1–13: Selection of finds from Pit A/14

In F. Gogâltan's view, Vatya I is co-eval with his Horizon 3 of the tell culture development (the turn of the EBA 3 and the MBA 1; ca. 2300–1950 BC), Vatya II with Horizon 4 (MBA 2; ca. 1900–1700 BC) and Vatya III with Horizon 5 (MBA 3; ca. 1650–1500 BC).⁴⁶

I. Bóna outlined a different chronological scheme in the catalogue accompanying the exhibition *Bronzezeit in Ungarn*.⁴⁷ Drawing on an outdated Bronze Age chronology, he proposed a general chronology for the Vatya culture, which in his view spanned the period between ca. 1650 and 1350 BC.⁴⁸ In this chronology, Vatya I and Vatya

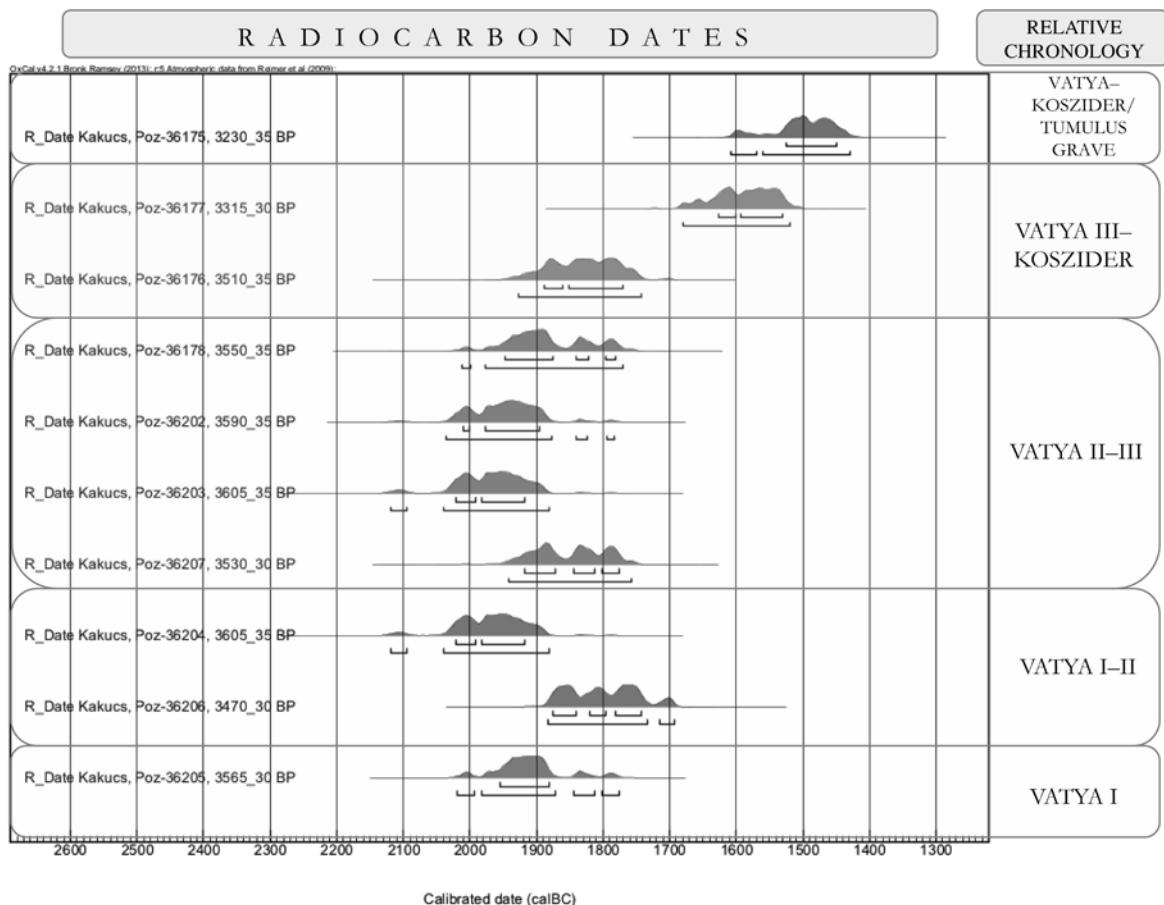

Fig. 19. Kakucs–Balla-domb. The sum of the probability distribution of the radiocarbon dates for Phases I–II–III and the Koszider period of the Vatya culture (JAEGER 2011)

II were linked to the MBA 1, Vatya III to the MBA 2, and the late variants (Vatya–Koszider, Alpár, Rákospalota and late Vatya–Koszider) to the MBA 3.⁴⁹

In her assessment of the Dunaujváros–Duna-dűlő cemetery, M. Vicze outlined the following sequence and relative chronology for the burial ground (although without assigning absolute dates to individual periods): formative Vatya–Kisapostag 2 (EBA 3; RB A1), Vatya I–Kisapostag 3 (MBA 1; RB A1), Vatya II, Vatya II–III (MBA 2; RB A2), early and late Koszider phase (MBA 3; RB B1), Rákóczifalva group–Tumulus culture (LBA 1; RB B2).⁵⁰

Some of the Vatya sites were occupied continuously from the Early Bronze Age onward (the Nagyrév culture).⁵¹ The available stratigraphic data indicate that during the initial and the early Vatya occupation, these sites were open settlements and that fortifications were mainly constructed during the late Vatya period.⁵² Other settlements, however, were demonstrably established during the late Vatya period.⁵³

As mentioned above, the decline of fortified settlements and, more broadly, the collapse of the tell cultures of the Carpathian Basin are generally linked to the Koszider period. Traditionally, the abandonment of the tell sett-

⁴⁹ BÓNA 1992a, 17; DAVID 2002, 30, Abb. 2. 6.

⁵⁰ VICZE 2011, 156, Fig. 31. Currently, there are no absolute dates for the culture's cemeteries, and the Dunaujváros–Duna-dűlő burial ground is no exception. The typochronological analyses were based on the grave assemblages from these cemeteries. The lack

of radiocarbon dates can in part be attributed to the custom of cremating the dead.

lements is dated to the turn of the 15th and 14th centuries BC,⁵⁴ with the line most often drawn at ca. 1350 BC as marking the end of the occupation on fortified settlements.⁵⁵

Until recently, there were only a handful of radiocarbon dates, which did not enable an absolute dating of the Vatya sequence (see in Appendix).⁵⁶ The most complete list of radiocarbon dates appeared in the *Bronzezeit in Ungarn* catalogue mentioned above.⁵⁷ However, the information accompanying the dates lacks basic data such as the provenance of the samples within a particular site and the material on which the dating was performed. This is the main reason that they cannot be regarded as a sound basis for drawing conclusions. The likelihood of an erroneous interpretation based on these dates is amply illustrated by dates from Sample Bln-341 for Dunaújváros–Koszi-

⁵⁷ RACZKY–HERTELENDI–HORVÁTH 1992.

derpadlás and the dates for Bölcse–Vörösgyír/Vörösgyűrű. The former was obtained from charred grain which was reportedly recovered from layers associated with the Nagyrév culture.⁵⁸ The results of the measurements however gave a date more in line with the settlement's Vatya occupation (Bln-341; 3505 ± 80 BP, 1937–1740 [68.2%] cal BC, 2035–1624 [95.4%] cal BC).⁵⁹ However, this can no longer be clarified owing to the lack of any field documentation regarding the context of the sample. As far as the Bölcse dates are concerned, the technique of excavating a site by spade spits (the *Spatenstichtechnik*)⁶⁰ as was customary at the time, means that few, if any, reliable stratigraphic and contextual observations were made. The overall impression of a general chaos in the available information is further enhanced by the different dates specified for one sample in the available publications.⁶¹ This is illustrated by the dates given for the samples from Mende–Leányvár (Bln-1942) and Tószeg (Bln-1923). The discrepancy between the Mende dates is relatively small (20 years) and involves a laboratory error (3280 ± 45 BP⁶² vs. 3280 ± 65 BP⁶³), while the Tószeg dates are characterised by both a laboratory error (5 years) and a 100 years difference in the specified BP age (3490 ± 45 BP⁶⁴ vs. 3590 ± 50 BP⁶⁵).

The only information on the material of the samples comes from Dunaújváros (charred grain).⁶⁶ The dates published in the *Bronzezeit in Ungarn* catalogue were broadly associated with the Vatya culture, but without any reference to typochronology or a particular period in the Vatya sequence.⁶⁷ In view of the above, they contribute little to the refinement of the internal periodisation of the Vatya culture and the absolute chronology of the fortified settlements in the Vatya distribution.⁶⁸

The five radiocarbon dates for the Vatya culture published in the *Bronzezeit in Ungarn* catalogue obtained from samples collected at Bölcse (2 dates), Dunaújváros, Mende and Százhalombatta gave a date between ca. 2000–1600/1500 BC (*Fig. 20*).⁶⁹

Although several dates are available for the Koszider period, they come from a fairly extensive and culturally much more diverse area. The known dates are based on samples from sites of the Hatvan, Otomani–Füzesabony and Vatya cultures.⁷⁰ They demonstrate a relatively long period between 1950/1900–1500/1450 cal BC, grouped in two time brackets between ca. 1950/1900–1650 (95.4%) cal BC and 1650–1500/1450 (95.4%) cal BC (*Fig. 21*). Since there is virtually no information about the archaeological context of the samples, it is impossible to make any meaningful comment on the relative lateness of the date from Sample Bln-1217 from the Jászdózsa settlement (3105 ± 100 BP;⁷¹ 1496–1221 [68.2%] BC, 1612–1057 [95.4%] cal BC). What is crucial, however, is that this date, together with the latest one of the Kakucs–Balla-domb series (Poz-36175; 3230 ± 35 BP; 1526–1449 [68.2%] cal BC, 1608–1430 [95.4%] cal BC) falls after 1500 BC, indicating a late date for the decline of fortified settlements in the Carpathian Basin (*Table 1*).

Even though the dates quoted in the above lack any information on the archaeological context of the samples, they nonetheless suggest that the Koszider period and the cultural transformation associated with this period in the Carpathian Basin was more complex and lasted for fairly long period of time.⁷² Traditionally, the Koszider hoards are linked to the late phase of the Otomani–Füzesabony, Mădarovce and Vatya cultures. Hoards of this type were no longer deposited after the decline of these cultures, although some of the artefact types in them continued to be manufactured and used as shown by their typologically later types.⁷³

⁷³ NOVOTNÁ 1998, 357.

The recently obtained dates for Százhalombatta–Földvár, Érd⁷⁴ and Kakucs–Balla-domb⁷⁵ contribute to our knowledge of the chronological dimensions of the occupation on various Vatya settlements. A series of twelve dates spanning the period between 1900 and 1400 BC is now available for Százhalombatta (*Fig. 22*).⁷⁶ The samples from open settlement at Érd roughly fall into the same period.

Knowing that the Százhalombatta settlement was occupied throughout the Vatya sequence, the lack of precise information on the relation between the dates and a particular typological phase or stratigraphic level is particularly distressing. In the case of the ten dates for Kakucs–Balla-domb, we know that they can be associated with Vatya I–II, Vatya II–III and Vatya III–Koszider, and that they fall within the period from 2000/2050 to 1450 BC (*Fig. 19, Table 1*). At present, it is not possible to link the different sub-phases to absolute dates.⁷⁷ Aside from possible sampling errors, the separation of the successive typochronological phases/sub-phases within the Vatya sequence is also uncertain on the culture's settlements.⁷⁸ At present only so much can be said, that the occupation of the Kakucs settlement began around 2000/1900 BC. The dates for the early Vatya period (Vatya I–II) show a scatter between 2000/1900 and 1800/1700 BC. The currently known dates for the classical Vatya II–III period partly overlap with the early period, although most fall between 1900/1800 and 1800/1700 BC. The late Vatya III–Koszider period can be dated to around 1600–1500 BC. The date of final occupation phase, 1526–1449 (68.2%) cal BC, is indicated by the burial dug into the earlier occupation levels.

The reliability and accuracy of the radiocarbon-based chronology outlined above can only be confirmed by additional dates for the Vatya culture and the correlation of the Százhalombatta–Földvár series with specific occupation phases and Vatya sub-periods. The dates from Százhalombatta–Földvár and Kakucs–Balla-domb indicate that the decline of the Vatya culture lasted longer than the dates quoted from the *Bronzezeit in Ungarn* catalogue would suggest. The occupation of the (fortified) settlements can be maximally defined as spanning the period between 2000/1900–1500/1450 BC (*Appendix* and *Fig. 20*).

It must also be noted that it is still virtually impossible to determine the chronology of the key periods in settlement development: the Nagyrév/Vatya cultural transformation documented at some sites,⁷⁹ the date when the initially open Vatya settlements were fortified (e.g., at Dunaújváros, Százhalombatta–Földvár and Pákozd–Vár)⁸⁰ and the period when new fortified settlements appeared following the culture's expansion as postulated in Bronze Age studies (e.g., Alpár–Várdomb, Mende–Leányvár, Nagykörös–Földvár).⁸¹ Still, the increase in the number of radiocarbon dates available for a particular settlement (Százhalombatta–Földvár, Kakucs–Balla-domb) will no doubt remedy this situation. Building a full series of radiocarbon dates correlated with the complete stratigraphic sequence of individual sites will surely help to overcome the current obstacles in reconstructing the dynamics of fortified Vatya settlements.

ACKNOWLEDGEMENTS

This paper was supported by grants from Ministry of Science and Higher Education of the Republic of Poland (NN 109 217135); the National Science Centre of The Republic of Poland (2012/05/BS3/03714), the Hungarian Scientific Research Fund and the Hungarian Academy of Sciences. We would like to thank Zsolt Réti and Margit Szabados for the illustrations.
