Abstract. We searched for associations (not for families) amongst the near Earth asteroids (NEAs) and, similarly as in our previous study (Jopek 2011, Jopek 2012), a dozen groups of 10 or more members was found with high statistical reliability. We present some details of our most numerous finding, association Anza '2061' which, at the moment, incorporates 191 members.

Keywords. Minor planets

1. Data, method, result, implication

Applying the cluster analysis we made an extensive search amongst 18291 NEA's retrieved in June 2018 from the NEODyS-2 database (<http://newton.dm.unipi.it/neodys/>). The most numerous finding was Anza '2061' association which consists of 191 members. Probability that such grouping is a statistical fluctuation is less than 1%. In Figure 1 the orbits of Anza association are illustrated. In Table 1 the designations of its selected members are given. To quantify the orbital similarity we used D_H function (see Jopek 1993) and the similarity thresholds was determined by the statistical approach. Regardless of their origin, existence of such associations increase the NEAs collision probability with the Earth. Analogously to meteoroid streams, each year the Earth almost cross the orbits of such associations. This implies that searching for grouping amongst the NEA's is an important issue.

Figure 1. Association Anza '2061'. 191 NEAs of this group were identified: before 2012, 88 orbit on the left panel, and after 2012, 103 orbits on the right. This example shows, that we do not know really how many members incorporates the Anza association?

Table 1. Designations of selected 27 members of Anza '2061' association.

2061	52760	100085	100085	162183	222008	354030	363831	446826
